

SPECIFICATION

TO ALL WHOM IT MAY CONCERN:

BE IT KNOWN THAT J. STUART CUMMING, a citizen of the United States, residing at Laguna Beach, California, has invented a new and useful

LENS ASSEMBLY FOR DEPTH OF FOCUS

of which the following is a specification:

092444 054900

BACKGROUND AND SUMMARY OF THE INVENTION

The natural human lens provides only limited depth of focus, with clear vision only over a limited range of distance.

5 The present invention provides increased depth of focus by positioning an optic posteriorly in the eye by disposing it on a substantially rigid frame which is configured to vault posteriorly, thus enabling accurate viewing over a wider range of distances with greater distance between the cornea and the optic, and the further posteriorly the positioning of the optic, the higher the power of the optic, and the less the lens movement required for a given power change.

10 The frame may preferably have plate haptics with transversely extending loops at the outer ends of the haptics to engage peripheral portions of the capsular bag of the eye and center the lens. The haptics may preferably be such as that shown and described in Applicant's Patent No. 6,051,024, "Intraocular Lenses with Fixated Haptics".

15 The optic utilized with the invention is substantially smaller than the natural human lens. Whereas the natural human lens is about 5.0 mm in thickness, an optic utilized with the invention may typically be 1.0 mm, and may range between 0.5 mm and 20 1.5 mm. The optic may preferably be similar to that shown and described in Applicant's application Ser. No. 09/370,235, "Lens For Increased Depth of Focus".

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 26 is a partial elevational view of a portion of the lens of Fig. 23, showing lug portions at the outer ends of a bifurcated web portion.

DESCRIPTION OF PREFERRED EMBODIMENT

The present invention provides increased depth of focus by providing a relatively rigid frame with haptics extending oppositely to engage a perimeter or equator of a capsular bag, and having a central opening to accommodate an optic engaged on the frame and movable anteriorly relative to the frame.

Referring to Figs. 1 to 8, frame 10 comprises a central portion 12 which defines a relatively large opening 14, and haptics 16, 18 extending oppositely from the central portion with fixation loops 20, 22 extending transversely from their outer portions, as shown, to engage peripheral portions of capsular bag 23. Slots 24, 26 extend from outer edges of the respective haptics and across a major width of each haptic.

A lens 30 comprises an optic 32 from which extend relatively short extensions 34, 36 which terminate in generally cylindrical ridges 38, 40. The ridges are adapted to be engaged and retained in the slots 24, 26, as shown in Figs. 7 and 8, wherein they are retained in position by shoulders 27 which define enlarged portions of the slots 24, 26 (Fig. 2).

In the modified form of Figs. 9 and 10, posteriorly extending frame portions or bumps 42, position the optic 32 further posteriorly than it would otherwise be, thus to effect additional, enhanced depths of focus, as will be understood from the geometry

of the components.

In Figs. 7, 8 and 9, the frame 10 and lens 30 are shown retained in assembled relation.

The optic 32 is thinner than a natural optic of a human eye and may have a thickness between 0.50 mm and 1.5 mm and may typically be about 1.0 mm thickness. The optic may typically be similar to that shown and described in the above-mentioned application of Applicant.

In operation, the optic 32 is movable anteriorly of the eye under vitreous pressure upon constriction of the ciliary muscle. The contraction of the muscle produces vitreous pressure which tends to urge the optic toward or into the hole 14 of the frame. The optic typically need not extend through the opening 14, but only extend about 1.0 mm into the opening. The optic need only move 1.0 mm to effect a change of 1.5 to 2.0 diopters of power change. The relatively rigid frame and the vitreous pressure thus effect optic movement relative to the frame.

It may be noted that an advantage of the present invention is that utilization of the relatively rigid frame substantially eliminates need for administration to a patient of a substance such as atropine during a period following surgery. This eliminates a problem in practice relative to patients not taking atropine, as instructed, during a period following surgery in order to maintain

the ciliary muscle in a relaxed condition during fibrosis relative to end portions of haptics.

The transversely extending loops 20, 22 provide centration and to facilitate fixation of the optic in the general manner described in Applicant's Patent No. 6,051,024, entitled "Intraocular Lenses With Fixated Haptics".

The frame 10 may typically be formed of PMMA, polycarbonate, nylon, other relatively rigid material, platinum or gold. The lens 30 may preferably be formed of a flexible optical material, such as silicone, acrylic, ^{HEMA} ~~HEMA~~, hydrogel, etc.

To provide for the bending or folding of the frame, as shown in Fig. 12, for insertion through a relatively short slit in the eye of a patient, the frame may be formed of relatively soft material at portions of the frame which are folded to provide a narrower configuration for insertion through the relatively short slit of the eye. These features include notches 46, 48 (Fig. 11) which extend from respective slots 24, 26 toward the opening 14 of the frame, and substantially reduced portions 50, 52 outwardly of the slots 24, 26.

Referring to Figures 13-17, a lens 54 has features in common with the embodiment of Figures 7-11, and differs in having enlarged openings 56, 58 of the configuration shown, wherein an enlarged rounded portion of the opening extends to define

relatively narrow haptic portions 60, 62 wherein slots 64, 66 are defined to receive ridges 38, 40, as with the embodiment of Figs. 7-11. The defining of the narrow haptics portions facilitates bending of the lens about its longitudinal axis (Fig. 12). Fig. 17 shows a partial, exploded view of this embodiment.

Figs. 18 and 19 show an embodiment similar to that of Figs. 13-17 but wherein there is no enlarged opening in haptics 68, 70.

Referring to Fig. 17, a modified form of the ridges 38, 40 at the ends of the optic extensions are hollow with passages 76, 78 therethrough, as shown in Fig. 17. As indicated in the figure, this type of ridge portion enables the ridge portion to be compressed by application of pressure to facilitate installation and retention of the ridge in a slit 64 or 66.

Figs. 20-26 illustrate embodiments in each of which relatively rigid frame members have attached therebetween a web whereon is disposed an optic.

Figs. 20-22 show an embodiment 80 wherein a web 82 is secured to opposite frame members 84, 85, as by integral molding of the components, by fasteners 86, or spot-welding. An optic 88 may typically be formed integrally with the web. The rigid frame members include transversely extending end loops 90, 92, as shown, for centration of the optic in the capsular bag of an eye.

Figs. 23-26 illustrate an embodiment wherein spaced-apart relatively rigid frame arms 96, 98 have attached thereto end portions of arms of webs 100, 102 which extend oppositely from a haptic 104. The webs are typically formed integral with the optic. The webs have retention knobs 110, 112 on their end portions (Fig. 26) to engage in slots 106, 108 in the frame arms to secure and retain the web portions relative to the frame members.

Figs. 24 and 25 are side views, taken respectively at lines 24 and 25 in Fig. 23, showing the particular manner in which the lugs 110, 112 engage in the slots 106, 108, and the relation of the optic to the frame members.

It will be understood that various changes and modifications may be made from the preferred embodiments discussed above without departing from the scope of the present invention, which is established by the following claims and equivalents thereof.
